Introduction

Failed back surgery syndrome (FBSS) may be defined as persisting or relapsing back and/or leg pain due to several conditions after back surgery. FBSS incidence is estimated between 5-50% range after lumbar spine or vertebrae surgery (1). In the USA 7 million new low back pain sufferer appear each year and 200,000 of them are applied Lomber spinal surgery. 20% of them are re-operated by reason of lasting pain (2). So approximately 40,000 new FBSS cases occur in USA every year and relief of back and radicular pain symptoms of these patients becomes necessary. In our study; we aimed to evaluate the efficacy of epiduroscopy procedure for patients that had been diagnosed as failed back surgery syndrome with persisting back and leg pain.

Materials – Methods

28 patients who had admitted to Sakarya University Training Research Hospital between years 2013-2014 and had epiduroscopy indication were included in the study. Demographic data were recorded. Patients were taken to operating room and were given prone position. Antiseptic solution was used to clean the skin. Conscious sedation was administered via midazolam, fentanyl and propofol. Intervention site was anesthetized with 1% lidocaine. After epiduroscopy was placed with Seldinger technique into sacral hiatus, epidurography was performed with 10 ml non ionic contrast agent. Fibrotic tissues were cleaned. The epidural adhesions were separated with epiduroscopy tip in epidural space. Patients were hospitalized one day and the day after procedure they were discharged from the hospital. Data of visual analog scale (VAS) scores, Oswestry disability Index (ODI) scores and neuropathic pain questionnaire (DN-4) scores were evaluated retrospectively. VAS, ODI and DN-4 scores before epiduroscopy and at 1st and 3rd months after the procedure were compared. SPSS IBM 20 program was used for the statistical analysis.

Results

Average age of the patients was 56.9 ± 15.65. When preoperative VAS scores were compared with postoperative 1st and 3rd month VAS scores; both postoperative VAS scores were significantly lower (p<0.05, Table-1). Similarly, alteration in DN-4 scores was in correlation with VAS and ODI scores (p<0.05, Table-1).

Conclusion

Epiduroscopy is a minimal invasive procedure that allows to direct visualization and treatment of the pathologies in epidural space. Besides, it’s useful for several therapeutic interventions like lysis of epidural adhesions, steroid injections, decompression of the epidural space for reducing the peri-radicular and dural inflammation and improving the physiological mobility of neural structures. We concluded that epiduroscopy was a method that reduced pain scores, improved functional status and the neuropathic pain level of the patients with FBSS.

Letter of Acceptance for E-Poster Category

Dear Dr. Ali Metin Ulgan,
Sakarya University education and research Hospital
Turkey

OMICS Group cordially invites you to attend the International Conference and Exhibition on Pain Medicine during June 08-10, 2015 at Chicago, USA.

We welcome you to join us and share your knowledge and views on the theme “Pain: Approaches to Predict, Control and Relieve”. On behalf of the Organizing Committee, we are pleased to welcome you for the upcoming international event. We are hereby informing you that E-Poster “Retrospective Comparison of Clinical Effect of Discogel Radiopaque Gelified Ethanol Application in Chronic Pain Related to Cervical Disc Hernia” “Efficacy of Epiduroscopy administration in patients with failed back surgery Syndrome” “Glossopharyngeal Nerve Neurolysis with alcohol: A case Report” has been accepted for the upcoming prestigious Pain Medicine-2015 conference

The International Conference and Exhibition on Pain Medicine initiated by Editors- Pain & Relief will offer you an unforgettable experience in exploring new opportunities.

We look forward to seeing you in Chicago.
